

Advanced Data Structure and Algorithm

Recurrence Relations and how to solve them!

Part-2

Understanding the Master Theorem

- Let $a \geq 1$, $b > 1$, and d be constants.

- Suppose $T(n) = a \cdot T\left(\frac{n}{b}\right) + O(n^d)$. Then

$$T(n) = \begin{cases} O(n^d \log(n)) & \text{if } a = b^d \\ O(n^d) & \text{if } a < b^d \\ O(n^{\log_b(a)}) & \text{if } a > b^d \end{cases}$$

- What do these three cases mean?

The eternal struggle

Branching causes the number
of problems to explode!
**The most work is at the
bottom of the tree!**

The problems lower in
the tree are smaller!
**The most work is at
the top of the tree!**

Consider our three recursive cases

1. $T(n) = T\left(\frac{n}{2}\right) + n$

2. $T(n) = 2 \cdot T\left(\frac{n}{2}\right) + n$

3. $T(n) = 4 \cdot T\left(\frac{n}{2}\right) + n$

First example: tall and skinny tree

$$1. T(n) = T\left(\frac{n}{2}\right) + n, \quad (a < b^d)$$

- The amount of work done at the top (the biggest problem) swamps the amount of work done anywhere else.

$$• T(n) = O(\text{work at top}) = O(n)$$

Third example: bushy tree

$$3. \quad T(n) = 4 \cdot T\left(\frac{n}{2}\right) + n, \quad (a > b^d)$$

WINNER

**Most work at
the bottom
of the tree!**

- There are a HUGE number of leaves, and the total work is dominated by the time to do work at these leaves.
- $T(n) = O(\text{work at bottom}) = O(4^{\text{depth of tree}}) = O(n^2)$

Second example: just right

$$2. \quad T(n) = 2 \cdot T\left(\frac{n}{2}\right) + n, \quad (a = b^d)$$

- The branching **just** balances out the amount of work.

- The same amount of work is done at every level.

- $T(n) = (\text{number of levels}) * (\text{work per level})$
- $= \log(n) * O(n) = O(n \log(n))$

What have we learned?

- The “Master Method” makes our lives easier.
- But it’s basically just codifying a calculation we could do from scratch if we wanted to.

The Substitution Method

- Another way to solve recurrence relations.
- More general than the master method.
- Step 1: Generate a guess at the correct answer.
- Step 2: Try to prove that your guess is correct.
- (Step 3: Profit.)

The Substitution Method

first example

- Let's return to:

$$T(n) = 2 \cdot T\left(\frac{n}{2}\right) + n, \text{ with } T(0) = 0, T(1) = 1.$$

- The Master Method says $T(n) = O(n \log(n))$.
- We will prove this via the Substitution Method.

$$T(n) = 2 \cdot T\left(\frac{n}{2}\right) + n, \text{ with } T(1) = 1.$$

Step 1: Guess the answer

- $T(n) = 2 \cdot T\left(\frac{n}{2}\right) + n$
 - $T(n) = 2 \cdot \left(2 \cdot T\left(\frac{n}{4}\right) + \frac{n}{2}\right) + n$
 - $T(n) = 4 \cdot T\left(\frac{n}{4}\right) + 2n$
 - $T(n) = 4 \cdot \left(2 \cdot T\left(\frac{n}{8}\right) + \frac{n}{4}\right) + 2n$
 - $T(n) = 8 \cdot T\left(\frac{n}{8}\right) + 3n$
 - ...
-

Guessing the pattern: $T(n) = 2^t \cdot T\left(\frac{n}{2^t}\right) + t \cdot n$

Plug in $t = \log(n)$, and get

$$T(n) = n \cdot T(1) + \log(n) \cdot n = n(\log(n) + 1)$$

$$T(n) = 2 \cdot T\left(\frac{n}{2}\right) + n, \text{ with } T(1) = 1.$$

Step 2: Prove the guess is correct.

- Inductive Hyp. (n): $T(j) = j(\log(j) + 1)$ for all $1 \leq j \leq n$.
- Base Case (n=1): $T(1) = 1 = 1 \cdot (\log(1) + 1)$
- Inductive Step:
 - Assume Inductive Hyp. for $n=k-1$:
 - Suppose that $T(j) = j(\log(j) + 1)$ for all $1 \leq j \leq k - 1$.
 - $T(k) = 2 \cdot T\left(\frac{k}{2}\right) + k$ by definition
 - $T(k) = 2 \cdot \left(\frac{k}{2} \left(\log\left(\frac{k}{2}\right) + 1\right)\right) + k$ by induction.
 - $T(k) = k(\log(k) + 1)$ by simplifying.
 - So Inductive Hyp. holds for $n=k$.
- Conclusion: For all $n \geq 1$, $T(n) = n(\log(n) + 1)$

We just replaced the "n" in the statement of the inductive hypothesis with an "k-1" to get the I.H. for k-1.

Step 3: Profit

- Pretend like you never did Step 1, and just write down:
- *Theorem: $T(n) = O(n \log(n))$*
- *Proof: [Whatever you wrote in Step 2]*

What have we learned?

- The substitution method is a different way of solving recurrence relations.
- Step 1: Guess the answer.
- Step 2: Prove your guess is correct.
- Step 3: Profit.

Another example

- $T(n) = 2 \cdot T\left(\frac{n}{2}\right) + 32 \cdot n$
- $T(2) = 2$
- Step 1: Guess: $O(n \log(n))$ (divine inspiration).
- But I don't have such a precise guess about the form for the $O(n \log(n))$...
 - That is, what's the leading constant?
- Can I still do Step 2?

Step 2: Prove it, working backwards to figure out the constant

- **Guess:** $T(n) \leq C \cdot n \log(n)$ for some constant C TBD.
- **Inductive Hypothesis:** $T(j) \leq C \cdot j \log(j)$ for $2 \leq j \leq n$
- **Base case:** $T(2) = 2 \leq C \cdot 2 \log(2)$ as long as $C \geq 1$
- **Inductive Step:**

$$T(n) = 2 \cdot T\left(\frac{n}{2}\right) + 32 \cdot n$$
$$T(2) = 2$$

Inductive step

- Assume that the inductive hypothesis holds for $n=k-1$.
- $T(k) = 2T\left(\frac{k}{2}\right) + 32k$
- $\leq 2C \frac{k}{2} \log\left(\frac{k}{2}\right) + 32k$
- $= k(C \cdot \log(k) + 32 - C)$
- $\leq k(C \cdot \log(k))$ as long as $C \geq 32$.
- Then the inductive hypothesis holds for $n=k$.

$$T(n) = 2 \cdot T\left(\frac{n}{2}\right) + 32 \cdot n$$
$$T(2) = 2$$

Step 2: Prove it, working backwards to figure out the constant

- **Guess:** $T(n) \leq C \cdot n \log(n)$ for some constant C TBD.
- **Inductive Hypothesis:** $T(j) \leq C \cdot j \log(j)$ for $2 \leq j \leq n$
- **Base case:** $T(2) = 2 \leq C \cdot 2 \log(2)$ as long as $C \geq 1$
- **Inductive step:** Works as long as $C \geq 32$
 - So choose $C = 32$.
- **Conclusion:** $T(n) \leq 32 \cdot n \log(n)$

$$T(n) = 2 \cdot T\left(\frac{n}{2}\right) + 32 \cdot n$$
$$T(2) = 2$$

Step 3: Profit.

- *Theorem:* $T(n) = O(n \log(n))$
- *Proof:*
 - **Inductive Hypothesis:** $T(j) \leq 32 \cdot j \log(j)$ for $2 \leq j \leq n$
 - **Base case:** $T(2) = 2 \leq 32 \cdot 2 \log(2)$ is true.
 - **Inductive step:**
 - Assume Inductive Hyp. for $n=k-1$.
 - $T(k) = 2T\left(\frac{k}{2}\right) + 32k$ By the def. of $T(k)$
 - $\leq 2 \cdot 32 \cdot \frac{k}{2} \log\left(\frac{k}{2}\right) + 32k$ By induction
 - $= k(32 \cdot \log(k) + 32 - 32)$
 - $= 32 \cdot k \log(k)$
 - This establishes inductive hyp. for $n=k$.
 - **Conclusion:** $T(n) \leq 32 \cdot n \log(n)$ for all $n \geq 2$.

Why two methods?

- Sometimes the Substitution Method works where the Master Method does not.

A fun recurrence relation

- $T(n) \leq T\left(\frac{n}{5}\right) + T\left(\frac{7n}{10}\right) + n$ for $n > 10$.
- Base case: $T(n) = 1$ when $1 \leq n \leq 10$

The Substitution Method

- Step 1: Guess what the answer is.
- Step 2: Prove by induction that your guess is correct.
- Step 3: Profit.

Step 1: guess the answer

$$T(n) \leq T\left(\frac{n}{5}\right) + T\left(\frac{7n}{10}\right) + n \text{ for } n > 10.$$

Base case: $T(n) = 1$ when $1 \leq n \leq 10$

- Trying to work backwards gets gross fast...
- We can also just try it out.
- Let's guess $O(n)$ and try to prove it.

Step 2: prove our guess is right

$$T(n) \leq T\left(\frac{n}{5}\right) + T\left(\frac{7n}{10}\right) + n \text{ for } n > 10.$$

Base case: $T(n) = 1$ when $1 \leq n \leq 10$

- Inductive Hypothesis: $T(j) \leq Cj$ for all $1 \leq j \leq n$.

- Base case: $1 = T(j) \leq Cj$ for all $1 \leq j \leq 10$

- Inductive step:

- Assume that the IH holds for $n=k-1$.

- $$\begin{aligned} T(k) &\leq k + T\left(\frac{k}{5}\right) + T\left(\frac{7k}{10}\right) \\ &\leq k + C \cdot \left(\frac{k}{5}\right) + C \cdot \left(\frac{7k}{10}\right) \\ &= k + \frac{C}{5}k + \frac{7C}{10}k \\ &\leq Ck ?? \end{aligned}$$

- (aka, want to show that IH holds for $k=n$).

- Conclusion:

- There is some C so that for all $n \geq 1$, $T(n) \leq Cn$

- Aka, $T(n) = O(n)$. (Technically we also need $0 \leq T(n)$ here...)

C is some constant we'll have to fill in later!

Whatever we choose C to be, it should have $C \geq 1$

Let's solve for C and make this true!
 $C = 10$ works.

Step 3: Profit

(Aka, pretend we knew this all along).

$$T(n) \leq n + T\left(\frac{n}{5}\right) + T\left(\frac{7n}{10}\right) \text{ for } n > 10.$$

Base case: $T(n) = 1$ when $1 \leq n \leq 10$

(Assume that $T(n) \geq 0$ for all n . Then,)

Theorem: $T(n) = O(n)$

Proof:

- Inductive Hypothesis: $T(j) \leq 10j$ for all $1 \leq j \leq n$.
- Base case: $1 = T(j) \leq 10j$ for all $1 \leq j \leq 10$
- Inductive step:
 - Assume the IH holds for $n=k-1$.
 - $$\begin{aligned} T(k) &\leq k + T\left(\frac{k}{5}\right) + T\left(\frac{7k}{10}\right) \\ &\leq k + 10 \cdot \left(\frac{k}{5}\right) + 10 \cdot \left(\frac{7k}{10}\right) \\ &= k + 2k + 7k = 10k \end{aligned}$$
 - Thus IH holds for $n=k$.
- Conclusion:
 - For all $n \geq 1$, $T(n) \leq 10n$
 - (Also $0 \leq T(n)$ for all $n \geq 1$ since we assumed so.)
 - Aka, $T(n) = O(n)$, using the definition with $n_0 = 1, c = 10$.

What have we learned?

- The substitution method can work when the master theorem doesn't.
 - For example with different-sized sub-problems.
- Step 1: generate a guess
 - Guess the rough estimate using back tracking.
- Step 2: try to prove that your guess is correct
 - You may have to leave some constants unspecified till the end – then see what they need to be for the proof to work!!
- Step 3: profit
 - Pretend you didn't do Steps 1 and 2 and write down a nice proof.
